Esteban Szalay

Advisor Dr. Jonathan Clark

#### **Instructors**

Dr. Nikhil Gupta Dr. Chiang Shih

Sponsor Jeff Phipps

**Constrictive Force Generation** 

Wheel Orientation

Summary

## Project Overview

Every year, 200 people are killed in tree related incidents.

The average cost for removing a fallen tree is between \$500-1000.

• This does not include repair cost.

The cost of cutting the tree itself is \$150-1500.

Goal Statement:

 Build a remotely operated snake-like robot that will safely climb trees.

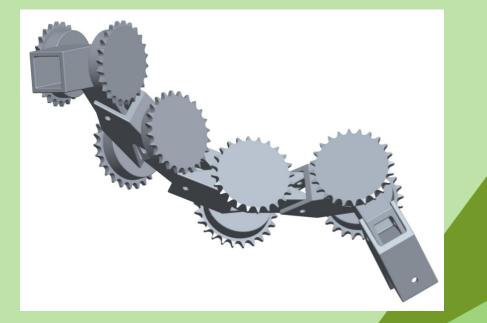

#### Objectives

- 1.5 times the length of circumference
- Must climb at a minimum of 60ft/hr
- Carry a 20lb payload

**Tentative Design** 

 Motorized Modular Aluminum Robotic Snake

## Design Considerations – Steps

#### Objectives

- 1.5 times the length of circumference
- Must climb at a minimum of 60ft/hr
- Carry a 20lb payload

- 1. Helical shape generation
- 2. Clamping mechanism
- 3. Climbing Speed
- 4. Branch Avoidance

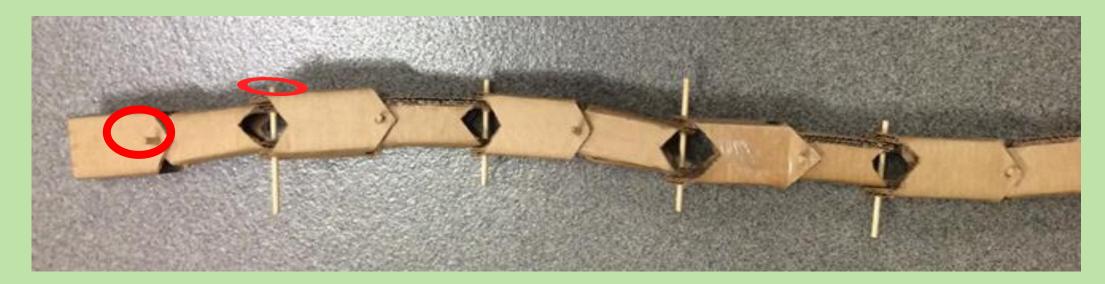

Constrictive Force Generation

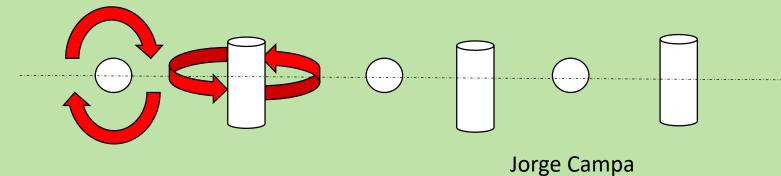

Wheel Orientation

Summary

## Helical Shape Generation

• Test joint design as alternating degrees of freedom (DOF)

Constrictive Force Generation

Wheel Orientation

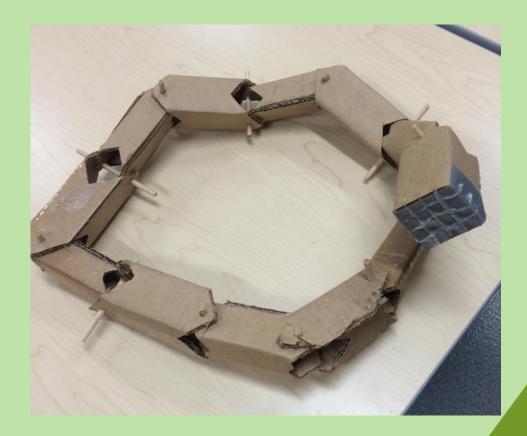

Summary

#### Motivating Questions and Assumptions

How to coil into a helix?

How do modules act individually and as a whole?

Assumed: Wheels and clamping do not affect the helical structure

Constrictive Force Generation

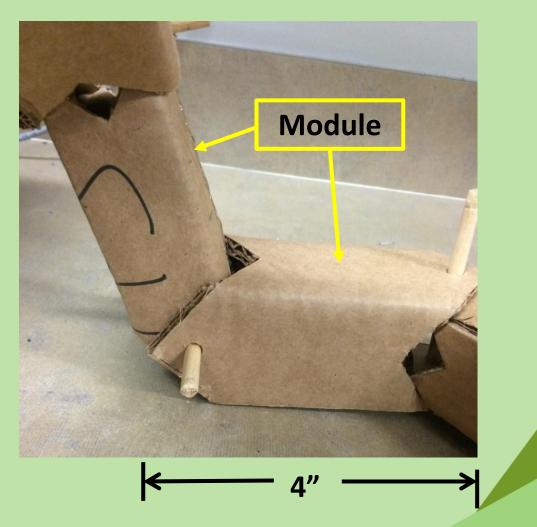

Wheel Orientation

Summary

#### Test and Results

Tested range of motion of each of the joints by flexing them to their limit

Found that triangular cut out limited range of motion of each of the joints individually

Constrictive Force Generation

Wheel Orientation

Summary

#### Test and Results

Tested the shape and structure of the snake robot when coiled

Realized that the snake did not coil into a perfect circle.

• Sharp turns could affect clamping

Constrictive Force Generation

Wheel Orientation

Summary

#### Design Modifications

From these results, we want to:

- Make joint cutouts square
- Make modules smaller and to scale:

Diameter of tree = d

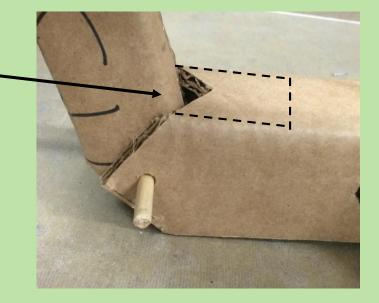

*Circumference of tree* = C = pi \* d

Length of snake = 1.5 \* C = 1.5 \* pi \* d

Length of module =  $\frac{\text{Length of snake}}{\# \text{ of modules desired}}$ 

*Diameter* = 5*in*; *Modules Desired* = 8 *cnt* 

Length of module  $\approx$  3in

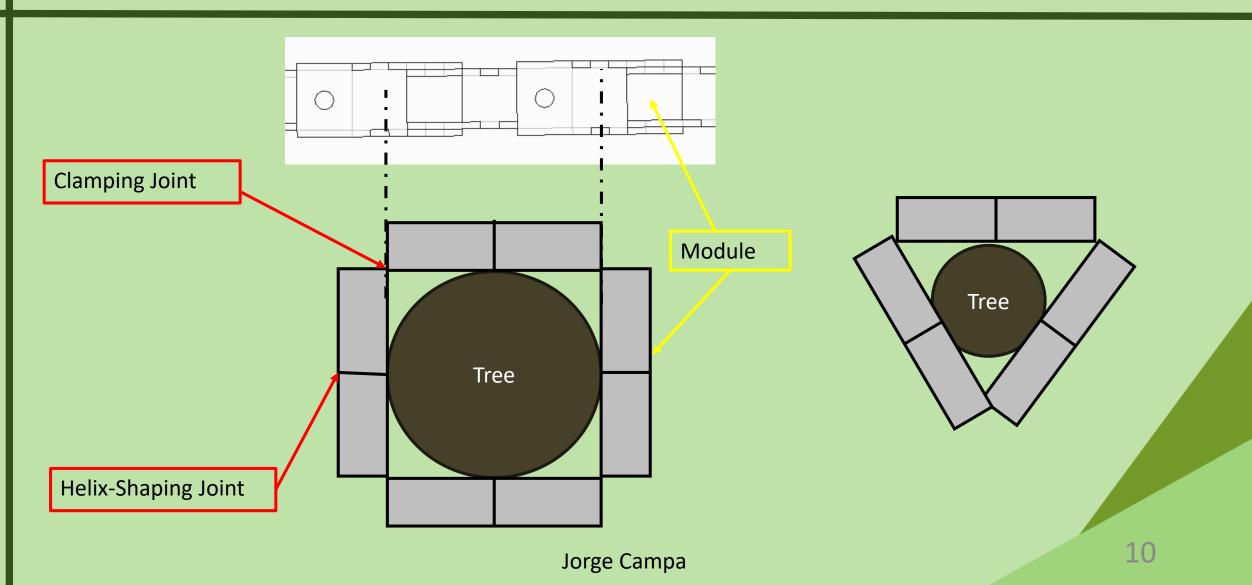

Constrictive Force Generation

Wheel Orientation

Summary

#### **Design Modifications**

Summary

#### Pneumatics

Pneumatics use a combination of oil and air

Rubber seals can break

• Replacing is hard and costly

Small leaks could mean immediate failure of the entire system, not the section

Summary

#### Soft Actuators

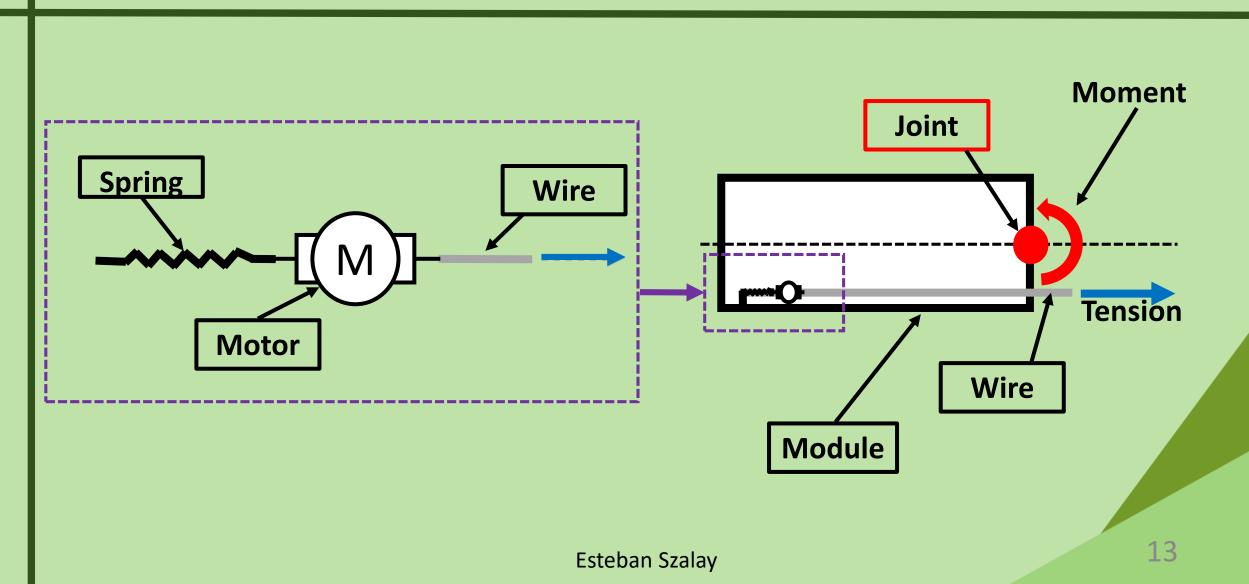

A prototype was created to test reliability in strength and flexibility

Flexibility was proven good but limited

When tested at high pressure the soft actuator burst rendering it defective.

## **Tension Inducing Wire**

Constrictive Force Generation

Wheel Orientation

Summary

#### Motivating Questions and Assumptions

Can the clamping mechanism hold the snake robot's weight?

How are wheels oriented when helically clamped?

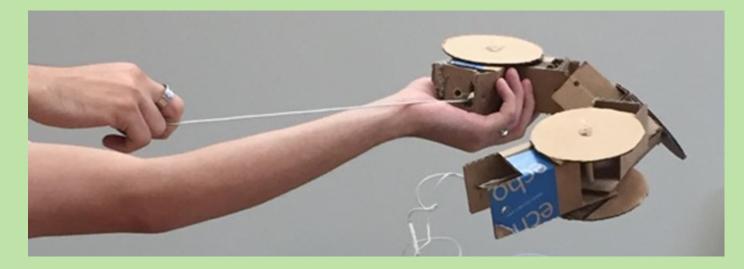

Assumed: wheel placement is independent of clamping mechanism

#### Test and Results

Clamping mechanism was pulled and showed promise on having snake curl

#### However, it acted unpredictably when pulled from rest

Wheel Orientation

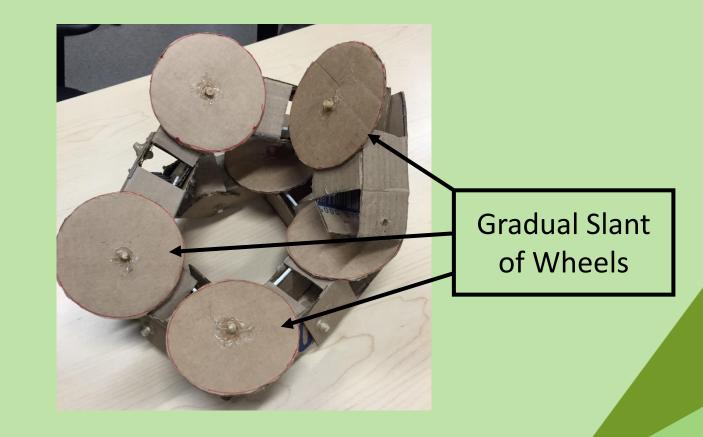

Summary

#### Test and Results

Joints were bent to their maximum angular displacement

Range of motion improved

Wheels were misaligned on tree surface

Constrictive Force Generation

Wheel Orientation

Summary

#### Test and Results

Constrictive Force Generation

Wheel Orientation

Summary

#### **Design Modifications**

Clamping mechanism made wheels turn away from tree Add degree of freedom that will align wheels to surface

Helical shape was generated but lacked consistency in shape

Have modules align themselves into proper helical shape

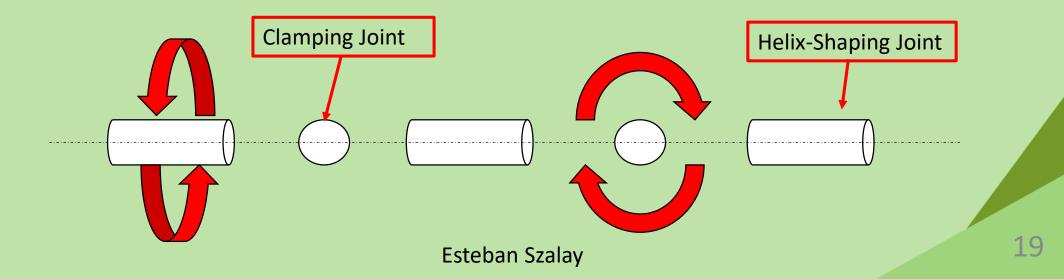

Esteban Szalay

Summary

#### Motivating Questions and Assumptions

Can the wheels align with the tree properly with the new degree of freedom?

Assumed: Clamping Mechanism is unaffected

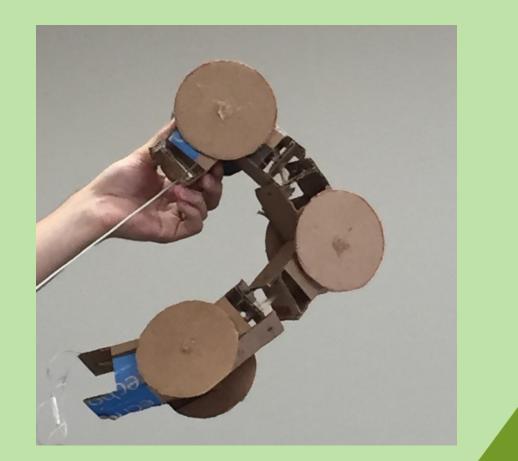

#### Test and Results

Tested alignment of wheels when curled

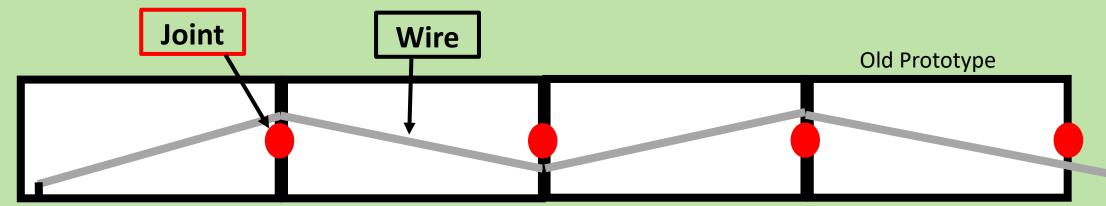

• Wheels aligned properly with cylindrical surface

Clamping mechanism failed to operate due to errors in construction

#### **Design Modifications**

#### Clamping mechanism did not provide sufficient tensile force

Change the alignment of the wire

New Prototype

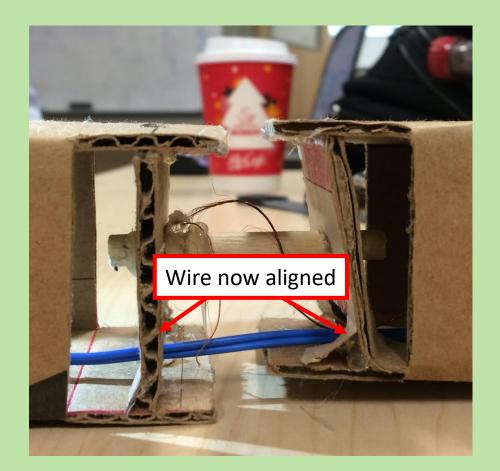

Wheel Orientation

Summary

#### Motivating Questions and Assumptions

Did the quick fix solve the clamping issue?

Assumption: Wheel design and placement independent of clamping

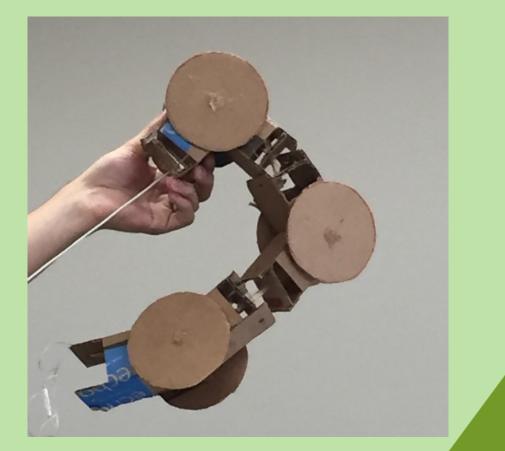

#### Test and Results

Tested module's alignment when curled into a helix

Modules were now aligned properly

String still may tangle when achieving helical motion

Wheel design still not specified

**Constrictive Force Generation** 

Wheel Orientation

Summary

#### Test and Results

Tension requirements outweigh structural integrity of cardboard prototype.

Modules bent beyond repair.

Esteban Szalay

Wheel Orientation

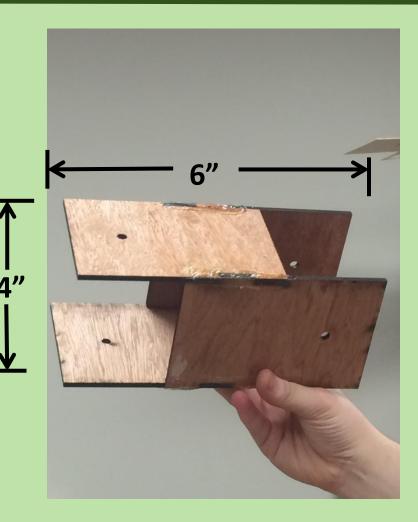

Summary

## Design Modifications / Upgrade

Add guide for wire (similar to a pulley)

Test actual clamping capabilities with the new orientation

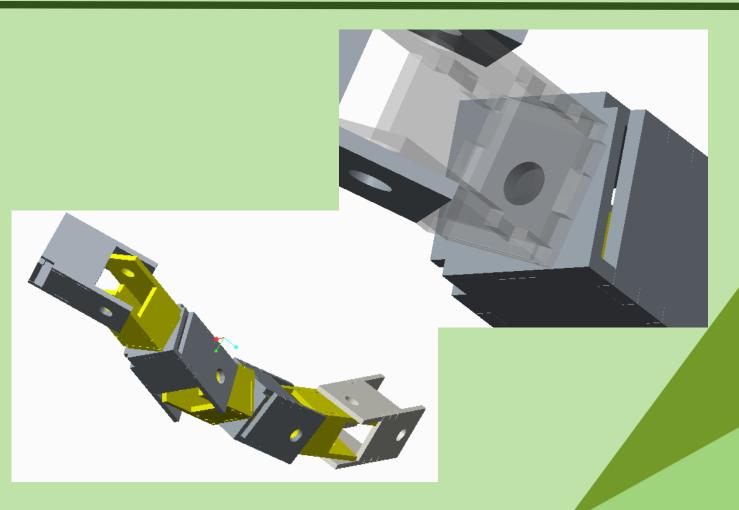

Make it of a sturdier material - wood

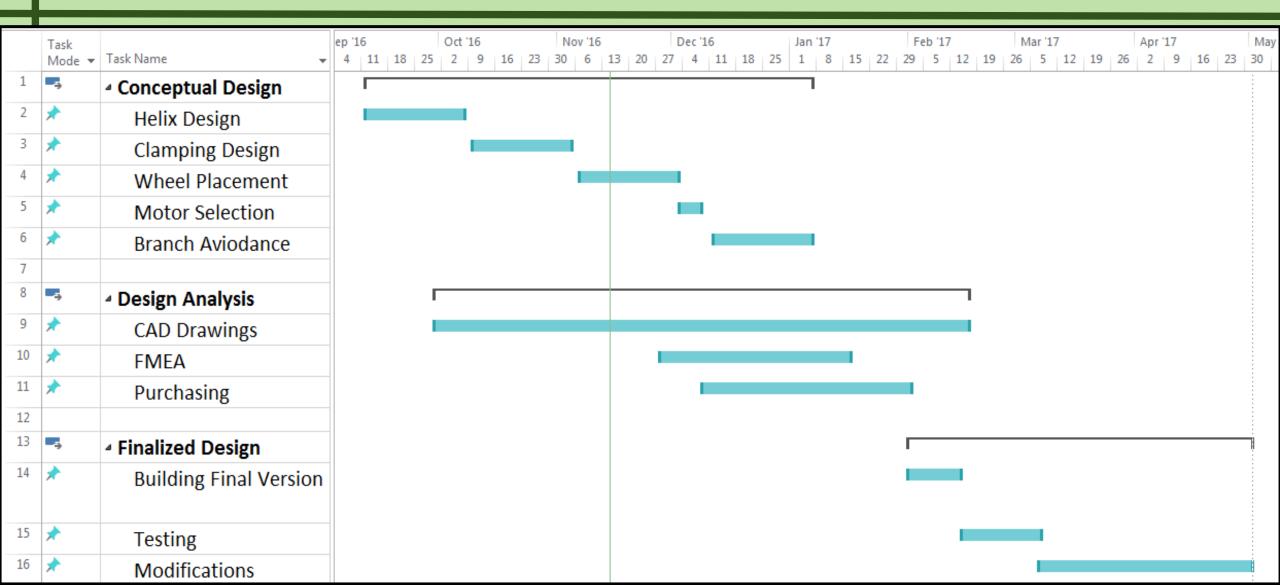

## Plan for the future

# 3<sup>rd</sup> Prototype to be built out of wood

- Laser cutter to be used
- Jigsaw Design to be used for links and assemble modules

## Plan for the future

### Plan for the future

#### Summary

#### We built two prototypes:

- 1. Module Interaction in Helical Shape formation
- 2. Clamping Mechanism and Wheel Placement

Next stage is to build a sturdier prototype to do the following:

- Simulate Clamping mechanism
- Helical shape generation
- Motion while in helical configuration

Simulate controlling velocity of dc motor with Arduino<sup>™</sup> microcontroller

# Questions?
