# PROJECT OVERVIEW

FAMU-FSU COLLEGE OF ENGINEERING  
MECHANICAL ENGINEERING

# Overview

## ➤ Project Summary

- Create a calendar that runs continuously for 100 years
  - Must utilize all-mechanical workings
  - No electrical input power
  - Annual maintenance allowed

Alyna Segura-Sanchez

FAMU-FSU COLLEGE OF ENGINEERING  
MECHANICAL ENGINEERING

# Overview

## ➤ Project Scope

- Create an operational 100-year mechanical calendar prototype out of inexpensive materials that accounts for the day, month and year, with annual maintenance.
- The prototype developed is to simulate proper date keeping and will be utilized by future senior design teams to improve upon.

# Overview

## ➤ Customer Needs

- Mechanism powered mechanically.
- Mechanism accounts for leap years and non-leap years.
- Internal workings visible from a distance.
- Usage of cost-effective materials while not sacrificing quality.
- Compact mechanism that is self-sufficient for a year at a time.

Alyna Segura-Sanchez

FAMU-FSU COLLEGE OF ENGINEERING  
MECHANICAL ENGINEERING

# Target Catalog

Table 1: Target Metrics

<u>Metric</u>	<u>Measure</u>	<u>Target</u>
Max allowable error	Time	1 day/year
Life span of mechanism	Time	100 years
Weather-proof rating	Durability	IP-55
Maintenance interval	Reproducibility	Annual
Max mechanism size	Dimensions	Door way
Furthest distance the date is legible	Visibility	3 meters
Organized design	Aesthetics	N/A
Amount of movements per day	Quantity	1
Tamper-proof rating	Durability	TL-40

# OUR PROTOTYPE

FAMU-FSU COLLEGE OF ENGINEERING  
MECHANICAL ENGINEERING

# Display Drawings

- Bought calendar drawing file
  - Not 3D
  - One page of drawings
  - Not all lines connected
- Prepared drawings for cutting
  - Placed same thickness on individual pages
  - Removed unnecessary labels

Figure 2: 3/8 in CAD drawings

# Display Material

## ➤ Material choices

- Wood
- Acrylic
- Stainless Steel
- Polycarbonate

## ➤ Why Polycarbonate?

- Light
- Weather resistant
- Shatter resistant

Figure 3: 3/4 in water jetted parts

# Manufacturing Display Parts

- Considered multiple options
  - 3D printing
  - Laser cutting
  - Water jetting
- 3D printing required extruding
- Laser cutter not strong enough
- Decided on waterjet

Alyna Segura-Sanchez

FAMU-FSU COLLEGE OF ENGINEERING  
MECHANICAL ENGINEERING

# Cutting Display Parts

- Water jetting
  - Looked at Engineering waterjet (too small)
  - Ended up using HPMI waterjet
- Water jetting of the display should finish by the end of the day
- Assembly of the display should finish by the end of the following week

Figure 4: HPMI waterjet

# Display-Clock Connection

- Whitworth quick return
- Connects clock to main lever of display

Figure 5: Calendar drawing

Figure 6: Whitworth quick return example

Jacob Williams

FAMU-FSU COLLEGE OF ENGINEERING  
MECHANICAL ENGINEERING

# The Clock

- 1952 Kundo All-Mechanical, Torsional Pendulum Clock
- 400 day run time
- Simple, yet elegant
- Easy rewinding mechanism

Figure 7: Kundo All-Mechanical Torsional Pendulum Clock

# Energy System

- Bellows modeled after those found on an Atmos clock
- Slight changes in temperature and pressure cause ethyl chloride gas to expand
- Utilizes most consistent environmental changes

Figure 8: Atmos bellows

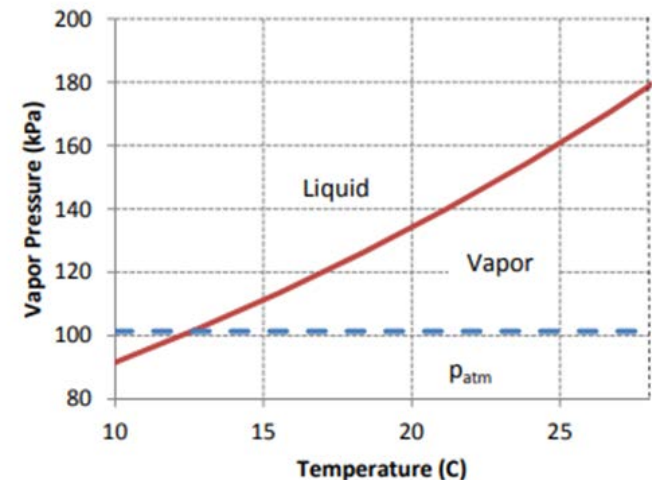

Figure 9: P-T graph of ethyl chloride

# Bellows Motion

- Winding drum picks up slack when bellows expands
- When the bellows contracts, it pulls the winding chain and winds the mainspring through a click and ratchet system
- Atmos clock in Tallahassee will produce at least 36.1 days of power on average

Figure 10: Atmos winding system

# Bellows Test

- Analysis of Bellows will occur before implementation into the final prototype
- Maximum height differences will be compared throughout the day

Figure 11: Atmos bellows expanded (back) and contracted (front)

# Next Steps

- Attach a stepper motor to the prototype to run at an accelerated rate.
  - Allows sponsors and following groups to see the flaws in our system.
- Design and manufacture an encasement able to withstand the Florida climate.
- Decrease overall size
- Increase aesthetic appeal

# Gantt Chart

Figure 12: Gantt Chart

MECHANICAL ENGINEERING

# Bellows Motion

- Pressure of ethyl chloride in the bellows creates a force,  
 $f_b = a_b p_b$
  - Two springs oppose bellow's force to recompress it,  $f_s = k_s x$
  - Winding drum picks up slack when bellows expands
  - When the bellows contracts, it pulls the winding chain and winds the mainspring through a click and ratchet system
- Pressure of ethyl chloride in the bellows creates a force,  
 $f_b = a_b p_b$
  - Two springs oppose bellow's force to recompress it,  $f_s = k_s x$
  - Winding drum picks up slack when bellows expands
  - When the bellows contracts, it pulls the winding chain and winds the mainspring through a click and ratchet system

Figure 9: Atmos winding system

# Energy System (cont.)

## ➤ Temperature changes

- The bellows on an Atmos clock generate about 4 days of power per °C
- Minimum temperature change in Tallahassee on average is 15 °F (~8.34 °C)
- Atmos clock in Tallahassee will produce at least 36.1 days of power on average

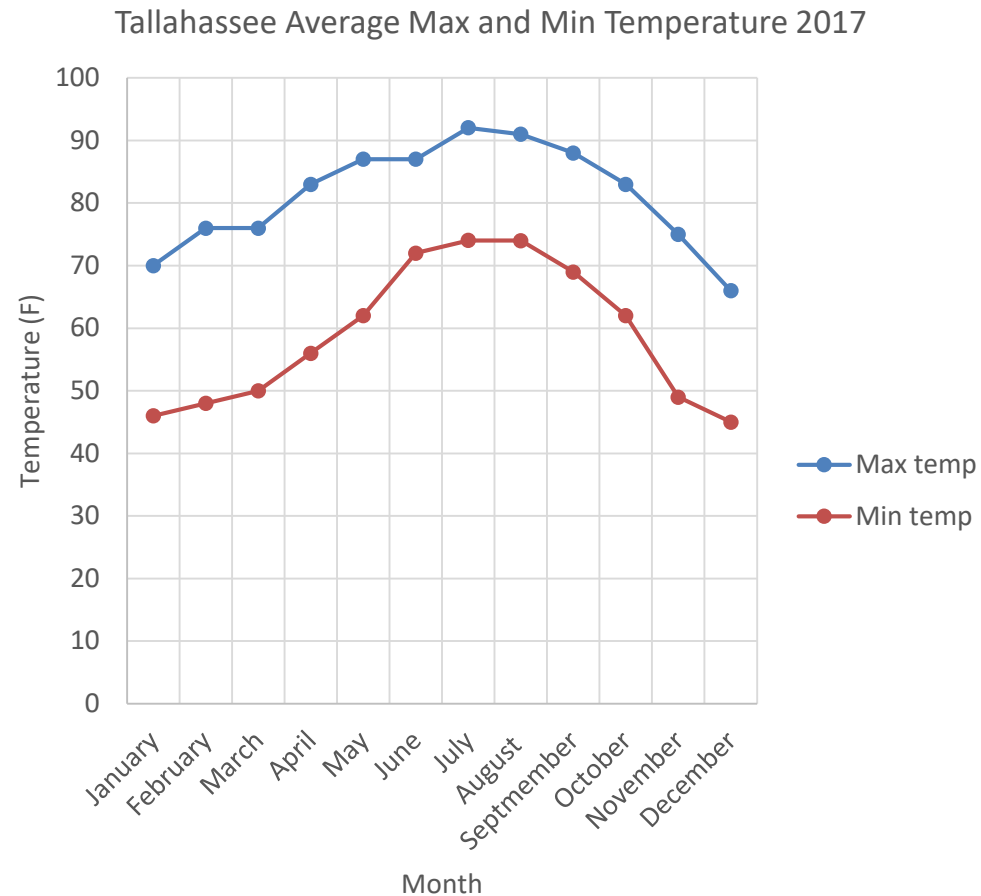

Figure 5: Temperature fluctuations per month in Tallahassee

Michael Patrick

FAMU-FSU COLLEGE OF ENGINEERING  
MECHANICAL ENGINEERING

# Energy System (cont.)

- Air temperature vs. atmospheric pressure power contribution
  - 37 mmHg (1.46 inHg) is a comparable to a temperature change of 1 degree C
  - Max average pressure change = 1.45 inHg, min average pressure change = 0.33 inHg
  - Pressure differential will power Atmos clock between 4.33 and 0.953

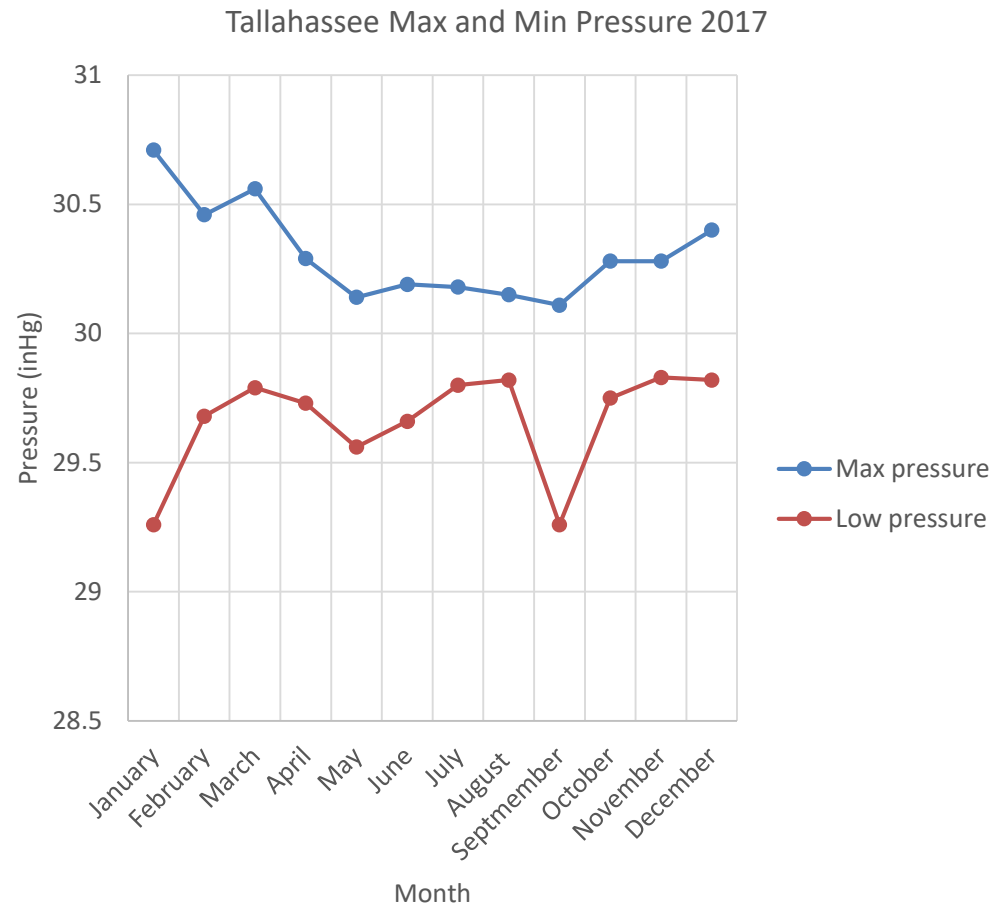

Figure 6: Pressure fluctuations per month in Tallahassee

# Ethyl Chloride Gas

- At room temp. and atmospheric pressure, ethyl chloride is a vapor
- Bellows is at min. volume at vapor/liquid point (boiling point)
- Most of the gas is a vapor at atmospheric pressure, so the increase in pressure may follow the ideal gas law,  $PV = nRT$

Pressure-temperature graph of ethyl chloride

# Mainspring

- Mainspring stores energy produced by bellows to drive the clock and the display

- Drive torque expressed as:

$$\tau = \frac{Eb_{ms}h_{ms}^3(\theta - \theta_0)}{12L} + \tau_0 \text{ where}$$

$E$ =modulus of elasticity,

$b_{ms}$ =mainspring width,

$h_{ms}$ =mainspring thickness,

$L$ =spring length

- $\tau_0 = Fd = (ma)d$
- Determine  $\tau_0$  by torqueing the mainspring

Mainspring example

# Mainspring Torque Calculation

- $\tau_0 = Fd = (ma)d$
- Make a jig comprised of a clamp to hold the mainspring
- Attach rod to mainspring
- Fully load mainspring
- Measure distance that a mass holds rod in the equilibrium position (horizontal)
- Plot torque for every 360 degree unwinding

# Clock Motion

- Use gear ratios to determine how long the clock can run
- *Gear ratio,  $R = \frac{N_{out}}{N_{in}}$*
- In, out denotes input and output motions
- Need number of teeth for each gear in the gear train
- Determine how long the great wheel takes for a full rotation
- *runtime = time to turn great wheel one rev \* number of revs to fully wind mainspring*

# Torsional Pendulum

- The time base of the clock regulated by simple harmonic motion
- The natural frequency is expressed by,  $\omega_n = \sqrt{\frac{k}{I}}$  where  $I = mr^2$
- The period is,  $T = \frac{2\pi}{\omega_n}$  where  $T = 60s$
- $k$  can be determined when the inertia is determined analytically
- Maintaining a 60s period is important because it keeps the timing of the clock

Torsional pendulum

# Energy Analysis

## ➤ Power consumption

- Determine the average torque produced

- $W = \tau\theta = \tau_{mean} \frac{2\pi}{rev}$

- $Power = \frac{W}{t}$

- $P = \frac{W}{(time\ to\ turn\ great\ wheel\ 1\ rev)}$

- For reference, an Atmos clock's average rate of power consumption is about  $0.0327\ \mu W$
- Losses due to pendulum, gear train, and escapement

# Energy Analysis (cont.)

- Temperature changes enough to power clock?
  - From Atmos experiment:
    - At room temperature, the bellows moved 1.63 mm/C (0.036 in/F) on average
    - Circumference of chain winder is 34 mm
    - $\left(\frac{360^\circ}{34 \text{ mm}}\right) \left(\frac{1.63 \text{ mm}}{^\circ\text{C}}\right) = \frac{17.3^\circ}{^\circ\text{C}}$
    - 55:18 gear ratio from chain winder to mainspring
    - $\left(\frac{17.3^\circ}{^\circ\text{C}}\right) \left(\frac{55}{18}\right) = \frac{52.9^\circ \text{ great wheel}}{^\circ\text{C}}$
    - For Atmos, full turn of great wheel takes 29.5 days
    - $\left(\frac{52.9^\circ}{^\circ\text{C}}\right) \left(\frac{29.5 \text{ days}}{360^\circ}\right) = \frac{4.33 \text{ days}}{^\circ\text{C}}$

# Energy Analysis (cont.)

  - From Atmos experiment:
    - At room temperature, the bellows moved 1.63 mm/C (0.036 in/F) on average
    - Circumference of chain winder is 34 mm
    - $\left(\frac{360^\circ}{34 \text{ mm}}\right) \left(\frac{1.63 \text{ mm}}{^\circ\text{C}}\right) = \frac{17.3^\circ}{^\circ\text{C}}$
    - 55:18 gear ratio from chain winder to mainspring
    - $\left(\frac{17.3^\circ}{^\circ\text{C}}\right) \left(\frac{55}{18}\right) = \frac{52.9^\circ \text{ great wheel}}{^\circ\text{C}}$
    - For Atmos, full turn of great wheel takes 29.5 days
    - $\left(\frac{52.9^\circ}{^\circ\text{C}}\right) \left(\frac{29.5 \text{ days}}{360^\circ}\right) = \frac{4.33 \text{ days}}{^\circ\text{C}}$

# Energy Analysis (cont.)

## ➤ Temperature changes (cont.)

- The bellows on an Atmos clock generates 4.33 days of power per degree C
- Minimum temperature change in Tallahassee on average is 15 degrees F (~8.34 degrees C)
- Therefore, an Atmos clock in Tallahassee will produce at least 36.1 days of power on average

# Energy Analysis (cont.)

- Air temperature vs. atmospheric pressure power contribution
  - 37 mmHg is a comparable to a temperature change of 1 degree C
  - 37 mmHg = 1.46 inHg
  - Maximum average pressure change in Tallahassee is 1.45 inHg
  - Minimum average pressure change is 0.33 inHg
  - At best, pressure differential will power Atmos clock for 4.33 days
  - At worst, pressure differential will power Atmos clock for 0.953 days

# Energy Analysis (cont.)

- Average temperature differential yearly = 21.5 degrees F = 12.0 degrees C
- Average pressure differential yearly = 2.64 inHg
- $\left(\frac{4.33 \text{ days}}{^{\circ}\text{C}}\right) (12.0 ^{\circ}\text{C}) = 51.96 \text{ days of power}$
- $\left(\frac{1.46 \text{ inHg}}{^{\circ}\text{C}}\right) \left(\frac{^{\circ}\text{C}}{4.33 \text{ days}}\right) \left(\frac{1}{2.64 \text{ inHg}}\right) = 0.1277 \text{ days of power}$
- Pressure differential only constitutes 0.25% of power supplied
- Note: as long as power supplied per month exceeds the length of the month, power will not run out
